NOTATION

- ▶ Real is a member of Cantor space 2^ω with topology with basic clopen sets $[\sigma] = \{\sigma\alpha : \alpha \in 2^\omega\}$ whose measure is $\mu([\sigma]) = 2^{-|\sigma|}$.
- ▶ Strings = members of $2^{<\omega} = \{0, 1\}^*$.
- ▶ There are theories for more general spaces, notably by Gács, (see his web site), but this is still under development. Certainly no lowness work.

PLAIN KOLMOGOROV COMPLEXITY

- ▶ Capture the incompressibility paradigm. Random means hard to describe, incompressible: e.g. 1010101010.... (10000 times) would have a short program.
- ▶ A string σ is random iff the only way to describe it is by hardwiring it. (Formalizing the Berry paradox)
- ▶ For a fixed machine N , we can define
- ▶ The **Kolmogorov complexity** $C(\sigma)$ of $\sigma \in \{0, 1\}^*$ with respect to N , is $|\tau|$ for the shortest τ s.t. $N(\tau) \downarrow = \sigma$. (Kolmogorov)

PLAIN KOLMOGOROV COMPLEXITY

- ▶ Capture the incompressibility paradigm. Random means hard to describe, incompressible: e.g. 1010101010.... (10000 times) would have a short program.
- ▶ A string σ is random iff the only way to describe it is by hardwiring it. (Formalizing the Berry paradox)
- ▶ For a fixed machine N , we can define
- ▶ The **Kolmogorov complexity** $C(\sigma)$ of $\sigma \in \{0, 1\}^*$ with respect to N , is $|\tau|$ for the shortest τ s.t. $N(\tau) \downarrow = \sigma$. (Kolmogorov)

- ▶ A string σ is N -random iff $C_N(\sigma) \geq |\sigma|$.
- ▶ A machine U is called weakly universal iff for all N , there is a d such that for all σ , $C_U(\sigma) \leq C_N(\sigma) + d$.
- ▶ Actually we will always use universal machines where the e -th machine is coded in a computable way.
- ▶ They exist (Kolmogorov). Hence there is a notion of Kolmogorov randomness for strings up to a constant. Define

$$U(1^e 0 \sigma) = M_e(\sigma).$$

This particular coding gives $C(\tau) \leq M_e(\tau) + e + 1$.

- ▶ We will often write $=^+$, where we mean $\pm O(1)$.

- ▶ A string σ is N -random iff $C_N(\sigma) \geq |\sigma|$.
- ▶ A machine U is called weakly universal iff for all N , there is a d such that for all σ , $C_U(\sigma) \leq C_N(\sigma) + d$.
- ▶ Actually we will always use universal machines where the e -th machine is coded in a computable way.
- ▶ They exist (Kolmogorov). Hence there is a notion of Kolmogorov randomness for strings up to a constant.
 Define

$$U(1^e 0 \sigma) = M_e(\sigma).$$

This particular coding gives $C(\tau) \leq M_e(\tau) + e + 1$.

- ▶ We will often write $=^+$, where we mean $\pm O(1)$.

- ▶ A string σ is N -random iff $C_N(\sigma) \geq |\sigma|$.
- ▶ A machine U is called weakly universal iff for all N , there is a d such that for all σ , $C_U(\sigma) \leq C_N(\sigma) + d$.
- ▶ Actually we will always use universal machines where the e -th machine is coded in a computable way.
- ▶ They exist (Kolmogorov). Hence there is a notion of Kolmogorov randomness for strings up to a constant. Define

$$U(1^e 0 \sigma) = M_e(\sigma).$$

This particular coding gives $C(\tau) \leq M_e(\tau) + e + 1$.

- ▶ We will often write $=^+$, where we mean $\pm O(1)$.

- ▶ A string σ is N -random iff $C_N(\sigma) \geq |\sigma|$.
- ▶ A machine U is called weakly universal iff for all N , there is a d such that for all σ , $C_U(\sigma) \leq C_N(\sigma) + d$.
- ▶ Actually we will always use universal machines where the e -th machine is coded in a computable way.
- ▶ They exist (Kolmogorov). Hence there is a notion of Kolmogorov randomness for strings up to a constant. Define

$$U(1^e 0 \sigma) = M_e(\sigma).$$

This particular coding gives $C(\tau) \leq M_e(\tau) + e + 1$.

- ▶ We will often write $=^+$, where we mean $\pm O(1)$.

- ▶ A string σ is N -random iff $C_N(\sigma) \geq |\sigma|$.
- ▶ A machine U is called weakly universal iff for all N , there is a d such that for all σ , $C_U(\sigma) \leq C_N(\sigma) + d$.
- ▶ Actually we will always use universal machines where the e -th machine is coded in a computable way.
- ▶ They exist (Kolmogorov). Hence there is a notion of Kolmogorov randomness for strings up to a constant. Define

$$U(1^e 0 \sigma) = M_e(\sigma).$$

This particular coding gives $C(\tau) \leq M_e(\tau) + e + 1$.

- ▶ We will often write \approx^+ , where we mean $\pm O(1)$.

DEFINITION

Thus we can define the **plain Kolmogorov complexity** of a string σ as $C(\sigma)$ for a fixed universal machine U .

- ▶ We can similarly do an oracle version of this and can define $C(x|y)$ as the Kolmogorov complexity of x **given** y . (And $C^A(x)$ for a set A)

PLAIN COUNTING THEOREM

- ▶ The following is the basic fact that makes the theory work.

THEOREM (PLAIN COUNTING THEOREM-KOLMOGOROV)

$$|\{\tau : C(\tau) \leq |\tau| - d\}| \leq O(1)2^{|\tau|-d}.$$

- ▶ Proof: pigeonhole principle.

DEFINITION (KOLMOGOROV)

We say that σ is **C-random** iff $C(\sigma) \geq |\sigma|$.

COMPLEXITY OSCILLATIONS

- ▶ Tempting but false $C(xy) \leq C(x) + C(y) + O(1)$. The false argument says : concatenate the machines
- ▶ The problem is where does x^* stop and y^* begin.
- ▶ Martin-Löf showed that the formula always fails for long enough strings and hence reals.

COMPLEXITY OSCILLATIONS

- ▶ Tempting but false $C(xy) \leq C(x) + C(y) + O(1)$. The false argument says : concatenate the machines
- ▶ The problem is where does x^* stop and y^* begin.
- ▶ Martin-Löf showed that the formula always fails for long enough strings and hence reals.

COMPLEXITY OSCILLATIONS

- ▶ Tempting but false $C(xy) \leq C(x) + C(y) + O(1)$. The false argument says : concatenate the machines
- ▶ The problem is where does x^* stop and y^* begin.
- ▶ Martin-Löf showed that the formula always fails for long enough strings and hence reals.

- ▶ Why? Take any α . Then, as a string $\alpha \upharpoonright n$ corresponds to some number which we can interpret as a string using Ilex ordering: $\alpha \upharpoonright n$ is the m -th string.
- ▶ Now consider the program that does the following. It takes a strings ν , interprets its length $m_\nu = |\nu|$ as a string, $\sigma = \sigma_m$ and outputs $\sigma\nu$.
- ▶ Apply this to the string τ whose length is m th code of $\alpha \upharpoonright n$.
- ▶ The output would be much longer, and would be $\alpha \upharpoonright m + n$, with input having length m . Thus $C(\alpha \upharpoonright m + n) < m + n - O(1)$.

- ▶ Why? Take any α . Then, as a string $\alpha \upharpoonright n$ corresponds to some number which we can interpret as a string using Ilex ordering: $\alpha \upharpoonright n$ is the m -th string.
- ▶ Now consider the program that does the following. It takes a strings ν , interprets its length $m_\nu = |\nu|$ as a string, $\sigma = \sigma_m$ and outputs $\sigma\nu$.
- ▶ Apply this to the string τ whose length is m th code of $\alpha \upharpoonright n$.
- ▶ The output would be much longer, and would be $\alpha \upharpoonright m + n$, with input having length m . Thus $C(\alpha \upharpoonright m + n) < m + n - O(1)$.

- ▶ Why? Take any α . Then, as a string $\alpha \upharpoonright n$ corresponds to some number which we can interpret as a string using lex ordering: $\alpha \upharpoonright n$ is the m -th string.
- ▶ Now consider the program that does the following. It takes a string ν , interprets its length $m_\nu = |\nu|$ as a string, $\sigma = \sigma_m$ and outputs $\sigma\nu$.
- ▶ Apply this to the string τ whose length is m th code of $\alpha \upharpoonright n$.
- ▶ The output would be much longer, and would be $\alpha \upharpoonright m + n$, with input having length m . Thus $C(\alpha \upharpoonright m + n) < m + n - O(1)$.

- ▶ The reason this kills the $C(xy) \leq^+ C(x) + C(y)$ is to apply this to a sufficiently long **random** $z = xy$ where
- ▶ $C(z) = p$, and $x = z \upharpoonright m + n$ (as above) and $y = z \upharpoonright [m + n + 1, |z|]$.
- ▶ Then $p > n + (p - (m + n)) - O(1) = p - m + O(1)$.

- ▶ This phenomenon is fundamental in our understanding of Kolmogorov complexity and is called **complexity oscillations**.
- ▶ There are several known ways to get round this problem to cause only to get the information provided by the **bits** of the strings.
- ▶ Telephone numbers!

UNIVERSAL COMPUTERS

- ▶ Levin, Gaács, Chaitin, Schnorr.
- ▶ Telephone numbers!!!!
- ▶ A computer M is **prefix-free** if

$$(M(\sigma)\downarrow \wedge \sigma' \supsetneq \sigma) \Rightarrow M(\sigma')\uparrow.$$

- ▶ A prefix-free machine is universal if every other one is coded in it.
- ▶ They exist, same proof.
- ▶ Now we have the *bits* of σ producing τ .

PREFIX-FREE RANDOMNESS

- ▶ Prefix freeness gets rid of the use of length as extra information: Machines concatenate!
- ▶ The **prefix-free complexity** $K(\sigma)$ of $\sigma \in \{0, 1\}^*$ is $|\tau|$ for the shortest τ s.t. $M(\tau) \downarrow = \sigma$.
- ▶ Note now $K(\sigma) \leq |\sigma| + K(|\sigma|) + d$, about $n + 2 \log n$, for $|\sigma| = n$.
- ▶ Build M , $M(z\sigma) = \sigma$ if $U(z) = |\sigma|$.

K-COUNTING THEOREM

THEOREM (COUNTING THEOREM-CHAITIN)

$$|\{\sigma : |\sigma| = n \wedge K(\sigma) \leq n + K(n) - c\}| \leq O(1)2^{n+K(n)-c}.$$

- ▶ As with life, relationships here are complex (Solovay)

$$K(x) = C(x) + C^{(2)}(x) + \mathcal{O}(C^{(3)}(x)).$$

and

$$C(x) = K(x) - K^{(2)}(x) + \mathcal{O}(K^{(3)}(x)).$$

- ▶ These 3's are **sharp** (Solovay) That is, for example, $K = C + C^2 + C^3 + \mathcal{O}(C^4)$ is NOT true.

- ▶ As with life, relationships here are complex (Solovay)

$$K(x) = C(x) + C^{(2)}(x) + \mathcal{O}(C^{(3)}(x)).$$

and

$$C(x) = K(x) - K^{(2)}(x) + \mathcal{O}(K^{(3)}(x)).$$

- ▶ These 3's are **sharp** (Solovay) That is, for example, $K = C + C^2 + C^3 + \mathcal{O}(C^4)$ is NOT true.

LOWNESS

- ▶ I would like to discuss the remarkable story of lowness.
- ▶ I will try to explain the **little boxes** method, which is new and poorly understood.
- ▶ Theme: to what extent do computational lowness (the extent to which sets resemble computable ones) and being far from random align themselves?

LOWNESS

- ▶ I would like to discuss the remarkable story of lowness.
- ▶ I will try to explain the **little boxes** method, which is new and poorly understood.
- ▶ Theme: to what extent do computational lowness (the extent to which sets resemble computable ones) and being far from random align themselves?

KEY FACTS

▶ THEOREM (CHAITIN)

There is a constant d such that for all c and all σ ,

$$|\{\nu : U(\nu) = \sigma \wedge |\nu| \leq C(\sigma) + c\}| \leq d2^c.$$

THEOREM (LEVIN, CHAITIN)

There is a constant d such that for all c and all σ ,

$$|\{\nu : U(\nu) = \sigma \wedge |\nu| \leq K(\sigma) + c\}| \leq d2^c.$$

- ▶ The **point** here is that d is independent of $|\nu|$ and depends only on the Recursion Theorem, and c

KEY FACTS

▶ THEOREM (CHAITIN)

There is a constant d such that for all c and all σ ,

$$|\{\nu : U(\nu) = \sigma \wedge |\nu| \leq C(\sigma) + c\}| \leq d2^c.$$

THEOREM (LEVIN, CHAITIN)

There is a constant d such that for all c and all σ ,

$$|\{\nu : U(\nu) = \sigma \wedge |\nu| \leq K(\sigma) + c\}| \leq d2^c.$$

- ▶ The **point** here is that d is independent of $|\nu|$ and depends only on the Recursion Theorem, and c

INFORMATION CHARACTERIZATION OF COMPUTABILITY

- ▶ Chaitin proved that a real A is computable iff for all n , $C(A \upharpoonright n) \leq^+ \log n$, iff $C(A \upharpoonright n) \leq^+ C(n)$.
- ▶ This is proven using the fact that a Π_1^0 class with a finite number of paths has computable paths, combined with the Counting Theorem $\{\sigma : C(\sigma) \leq C(n) + d \wedge |\sigma| = n\} \leq A2^d$. (The Loveland Technique)
- ▶ Loveland had earlier shown A is computable iff $C(A \upharpoonright n|n) \leq c$ for some c and all n .

- ▶ If $C(\alpha \upharpoonright n|n) \leq 5$ then there are only 5 programmes possibly computing initial segments of α .
- ▶ This computes a tree of *strings* of maximal width 5.
- ▶ Therefore only at most 5 paths. Say 4.
- ▶ Imagine the situation that there is only *one* path in a tree of maximal width 2.

K-TRIVIALITY

- ▶ What is $K(A \upharpoonright n) \leq^+ K(n)$ for all n ? We call such reals **K-trivial**. Does A K-trivial imply A computable?
- ▶ Write $A \in KT(d)$ iff for all n , $K(A \upharpoonright n) \leq K(n) + d$.

K-TRIVIALITY

- ▶ What is $K(A \upharpoonright n) \leq^+ K(n)$ for all n ? We call such reals **K-trivial**. Does A K-trivial imply A computable?
- ▶ Write $A \in KT(d)$ iff for all n , $K(A \upharpoonright n) \leq K(n) + d$.

THE ARGUMENT FAILS

- ▶ It is still true that $\{\sigma : K(\sigma) \leq K(|\sigma|) + d\}$ is $O(2^d)$, so it would appear that we could run the Π_1^0 class argument used for C . But no...
- ▶ The **problem** is that we don't know $K(n)$ in any computable interval, therefore the tree of K -trivials we would construct would be a Π_1^0 class **relative to \emptyset'** .

THEOREM (CHAITIN, ZAMBELLA)

There are only $O(2^d)$ members of $KT(d)$. They are all Δ_2^0 .

THEOREM (SOLOVAY)

There are noncomputable K-trivial reals.

THEOREM (ZAMBELLA)

Such reals can be c.e. sets.

A REMARKABLE CLASS

- ▶ *K*-trivials form a remarkable class as we will see.
- ▶ First they solve Post's problem.
- ▶ Theorem: (DHNS) If A is *K*-trivial then $A <_T \emptyset'$.
- ▶ See “The Sixth lecture” for details of the proof.

Similar methods allow for us to show the following

THEOREM (NIES)

*All K-trivials are superlow $A' \equiv_{tt} \emptyset'$, and are tt-bounded by c.e. K-trivials. In fact they are **Jump Traceable** as we see below.*

Thus triviality is essentially an “enumerable” phenomenon.

There are other antirandomness notions.

DEFINITION (KUČERA AND TERWIJN)

We say A is low for randomness iff the reals Martin-Löf random relative to A are exactly the Martin-Löf random reals.

DEFINITION (HIRSCHFELDT, NIES, STEPHAN)

A is a base of a cone of randomness iff $A \leq_T B$ with B A -random.

THEOREM

*The following are equivalent to being *K*-trivial.*

- (I) *(Nies) A is low for randomness.*
- (II) *(Hirschfeldt and Nies) A is *K*-low in that $K^A =^+ K$.*
- (III) *(Hirschfeldt, Nies, Stephan) A is a base of a cone of randomness.*
- (IV) *(Downey, Nies, Weber, Yu+Nies, Miller) A is low for weak-2-randomness.*

QUESTIONS AND A PROPER SUBCLASS

It is open if this is the same as a number of other “cost function” classes such as the reals which are Martin-Löf cuppable to \emptyset' .
(Nies)

It is known there is a proper subclass defined by cost function.

DEFINITION (NIES)

Let h be an order. We say that A is **jump traceable** for the order h iff there is a computable collection of c.e. sets $W_{g(e)}$ with $|W_{g(e)}| < h(e)$ and $J^A(e) \in W_{g(e)}$. A is **strongly jump traceable** iff it is jump traceable for **every** computable order.

THEOREM (NIES)

*A is *K*-triv implies that there is an order h (roughly $n \log n$) relative to which A is jump traceable.*

THEOREM (FIGUEIRA, NIES, STEPHAN)

Noncomputable sjt c.e. sets exist.

THEOREM (CHOLAK, DOWNEY, GREENBERG)

*The c.e. sjt's are a **proper** subclass of the *K*-trivials. They form an ideal.*

THEOREM (DOWNEY, GREENBERG)

If A is sjt then A is Δ_2^0

- ▶ Roughly need orders $\sqrt{\log n}, \log \log n$. Is there a combinatorial characterization?

THEOREM (NIES)

*A is *K*-triv implies that there is an order h (roughly $n \log n$) relative to which A is jump traceable.*

THEOREM (FIGUEIRA, NIES, STEPHAN)

Noncomputable sjt c.e. sets exist.

THEOREM (CHOLAK, DOWNEY, GREENBERG)

*The c.e. sjt's are a **proper** subclass of the *K*-trivials. They form an ideal.*

THEOREM (DOWNEY, GREENBERG)

If A is sjt then A is Δ_2^0

- ▶ Roughly need orders $\sqrt{\log n}, \log \log n$. Is there a combinatorial characterization?

THEOREM (NIES)

*A is *K*-triv implies that there is an order h (roughly $n \log n$) relative to which A is jump traceable.*

THEOREM (FIGUEIRA, NIES, STEPHAN)

Noncomputable sjt c.e. sets exist.

THEOREM (CHOLAK, DOWNEY, GREENBERG)

*The c.e. sjt's are a **proper** subclass of the *K*-trivials. They form an ideal.*

THEOREM (DOWNEY, GREENBERG)

If A is sjt then A is Δ_2^0

- ▶ Roughly need orders $\sqrt{\log n}, \log \log n$. Is there a combinatorial characterization?

- ▶ Conjecture : A is K -trivial iff A is jump traceable for all computable orders h with $\sum_{n \geq 1} \frac{1}{h(n)} < \infty$.

A HINT OF THE PROOF TECHNIQUES

- ▶ To show that if A and B are c.e. sjt, so is $A \oplus B$.
- ▶ We show h we can construct a slower order k such that if A and B are jump traceable via k then $A \oplus B$ is jump traceable via h
- ▶ Opponent gives: $W_{p(x)}$ jump tracing A and $W_{q(x)}$ jump tracing B , such that $|W_{p(x)}|, |W_{q(x)}| < k(x)$.
- ▶ We: V_z tracing $J^{A \oplus B}(z)$ with $|V_z| < h(z)$.

TWO OBSTACLES

- ▶ We see an **apparent** jump computation $J^{A \oplus B}(x) \downarrow [s]$.
- ▶ Should we believe? We only have $h(x)$ many slots in the trace V_x to put possible values.
- ▶ Opponent can change A or B after stage s on the use.
- ▶ We build parts of jump (recursion thm) testing A and B
- ▶ Basic idea: For some $a = a(x)$ and $b = b(x)$ we will define

$$J^B[s](b) = j_B(x, s) \text{ and } J^A[s](a) = j_A(x, s),$$

where $j_C(x, s)$ denotes the C -use of the $J^{A \oplus B}(x)[s]$ computation.

- ▶ Ignore *noncompletion*: that is the $A \oplus B$ computation changes **before** these procedures return.
- ▶ Simplest case: $W_{p(a)}$ and $W_{q(b)}$ were of size 1 (1-boxes)
- ▶ Then if return: $A \oplus B$ **is** correct
- ▶ Now 2-boxes. If the $A \oplus B$ computation is wrong, at least one of the A or B ones are too.

- ▶ If we are lucky and there is are false jump computations in **both** of the $W_{p(a)}$ and $W_{q(b)}$.
- ▶ The are now, in effect 1-boxes. (Very good)
- ▶ Can't allow to only point at one side. Use up all the 2-boxes.
- ▶ For example if always the A sides was the wrong part, and there were k 2-boxes then after k attacks, all the 2-boxes would be useless and the information in the B -side **is** correct, hence the box is used.

MULTIPLE BOXES

- ▶ Idea: use multiple 2-boxes. E.g. at the beginning use two 2-boxes for the **same** computation.
- ▶ A side was wrong. Then now we have *two promoted* 1-boxes.
- ▶ Since the *A*-computation now must be correct, if the believed computation is wrong, it must be the *B* side which wrong the next time, now creating a new *B*-1-box. Finally the third time we test, we would have two 1-boxes.

NON-RETURN

- ▶ Now we face the ignored problem. We test and **before** the computation retruns, the Jump computation is changed by an *A* or *B* change, but **possibly** one of the *A* or *B* uses **is** correct. Now **nothing** is promoted. This seems very bad.
- ▶ Even with 1-boxes.
- ▶ Use descending sequences of boxes, and big metaboxes.
- ▶ Complicated, combinatorial.

- ▶ The idea is that for a computation whose target is, say, 2-boxes, begin ever further out. Begin by testing at, say, s -boxes.
- ▶ Monster boxes called metaboxes.
- ▶ If **both** A and B return at the s -box, go to $s - 1$ etc. Only believe if you get back to the 2-boxes. The idea that a failure at k **promotes** $k + 1, \dots, s$ -boxes, at least on one side.
- ▶ A combinatorial argument if used to show that cannot favour one side forever.

- ▶ How to make a properly ω -c.e. *K*-trivial?
- ▶ Use **descending costs**....
- ▶ If the trace grows slowly enough then can make *K*-trivial and **not** jt at that order. Much the same idea, the key point being the to change the trace and use a a box location, the **use** is very big, and the opponent needs more tailweight.

THE GENERAL CASE

- ▶ We conjecture that all sjt's are bounded by c.e. sjts.
- ▶ They are all Δ_2^0 (Downey and Greenberg). This is a very difficult result.
- ▶ We can prove an apparently smaller class are all good in this sense, strongly well-approximable. (being written)

NG KENG MENG'S THEOREMS

- ▶ The c.e. sjt's are Π_4^0 complete.
- ▶ This solves a problem of Nies: there is no minimal order.

BEYOND JUMP TRACEABILITY

- ▶ Say A is **C-sjt** iff for all orders h^B , for $B \in C$, A is h^B -jt.
- ▶ (Ng) No real is C-sjt where $C = \Delta_2$.
- ▶ (Ng) There are c.e. reals sjt for all c.e. sets.
- ▶ (Ng) They cannot be promptly simple, the first such class.
- ▶ (Ng) **No** real is K^B -trivial for all B , or c.e. B .

WHY CAN'T THE BE PROMPT?

- ▶ The construction is really a $\mathbf{0}'''$ argument since we need to guess whether φ_e^W is really a trace. Like the proof that the sjt's are Π_4^0 complete this need the full apparatus of $\mathbf{0}'''$ method.
- ▶ (Ng) There are sjt A and B such that B is not A -sjt.

LOTS OF IGNORED WORK

- ▶ Use pseudo-jump inversion to talk about “ultrahighness”
- ▶ E.g. a proper subclass of the “almost everywhere dominating”
- ▶ cappable etc. (Ng)
